1. Introduction

There is no safe level of exposure to air pollution. Australia experiences levels of air pollution that significantly impact the health of our communities. Collective studies estimate that between 2,616 and 4,884 people die prematurely from exposure to air pollution every year in Australia.¹ The economic cost of premature death attributed to ambient air pollution in Australia has been estimated at up to AUD\$24 billion per year.² Low levels of exposure to air pollution can cause adverse health impacts,³ however the lower the pollution, the lower the health impacts. Driving pollution down to as close to zero as possible would have significant benefits.

This Clean Air Action Plan identifies the largest sources of controllable air pollution, and the actions that the NSW government must take to reduce it to best practice control standards. It has been developed in collaboration between health experts, environmental lawyers, community groups in areas impacted by air pollution, and international experts. We urge the NSW government to adopt this plan and the actions it lists throughout.

The overwhelming industrial source of air pollution in Australia and NSW is coal-fired power stations.⁴ The other major sources that contribute to health impacts are coal mining, motor vehicles and smoke from wood heaters.⁵ The most recent analysis of health impacts caused by coal-fired power stations in Australia has found that they contribute to 845 babies being born with low birth-weight, 14,434 children with asthma, and 785 premature deaths each year.⁶ The health cost to the Australian

economy from coal-fired power stations alone is \$2.4 billion dollars annually.⁷ Air pollution from coal-fired power stations disproportionately impacts communities living near coal-fired power stations, making this one of the most significant environmental justice issues in Australia. Air pollution reduction measures cannot only be undertaken primarily in larger population areas, such as metropolitan Sydney.

In 2005, the annual health cost of air pollution in the Sydney Greater Metropolitan Region (GMR) was estimated to be \$893 per head of population or \$4.7 billion,⁸ equivalent to \$6.4 billion a year in 2015 terms.⁹ The 2014 Impact Statement to the Draft Variation to the *National Environment Protection (Ambient Air Quality) Measure* noted that the savings in associated health costs of reducing ambient particulate matter concentrations in the NSW Greater Metropolitan region (GMR) was estimated to be \$5.7 billion per annum.¹⁰

The NSW government initiated the development of a Clean Air Strategy several years ago. The NSW population is exposed to significant amounts of air pollution each year. As the most populous state, reducing air pollution and lifting the health burden should be treated as a priority. Fortunately, the rest of the world has undertaken air pollution reduction measures that NSW can learn from and implement to protect public health.

The devastating bushfires of the 2019-2020 summer period and the ongoing COVID-19 global pandemic have highlighted air pollution as a significant public health problem. Research published in the *Medical Journal of Australia* estimates that more than 400 people died from exposure to air pollution during the fires,¹¹ with many more likely to have developed chronic illness, or experienced serious short-term health impacts.¹² The total estimated health costs of the bushfire smoke is \$1.95 billion.¹³ It is a matter of when, not if, Australia will experience severe bushfires again. Without reducing existing sources of air pollution to best practice control standards, the public health consequences of air pollution from subsequent bushfires will continue to be exacerbated, especially for those communities who are already exposed to high levels of air pollution throughout the year.

Air pollution can cause health problems like heart attacks, strokes, diabetes and high blood pressure, which have been identified as pre-existing medical conditions that raise the chances of death from COVID-19 infection.¹⁴ By implementing this Clean Air Action Plan, pre-existing sources of air pollution will be reduced which may assist in reducing health impacts from both these crises.

2. Air pollution

2.1 Pollutants and pollution sources

Industrial processes emit a broad range of pollutants that can impact health. It is generally accepted that there are five key pollutants released or formed in the atmosphere from numerous and diverse stationary and mobile sources that cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare. These pollutants are fine particle pollution (PM_{2.5}), coarse particle pollution (PM₁₀), oxides of nitrogen (NO_x), sulfur dioxide (SO₂), and ozone (O₃). These pollutants also represent the majority of air pollutants for which standards are set in the *National Environment Protection (Ambient Air Quality) Measure*.¹⁵ The health impacts of these pollutants are outlined below in section 2.5.

Particle pollution consists of tiny solid particles that come in a range of sizes, measured in micrometres. Coarse particle pollution is usually referred to as PM₁₀ (that is, particle size of 10 micrometres in diameter), which generally forms as dust (such as coal dust) and is inhalable into the lungs. Fine particle pollution, known as PM_{2.5}, is much smaller, at 2.5 micrometres in diameter. Its small size means it can get deeper into the lungs and into the bloodstream, causing a deadly range of health impacts (see section 2.5 below).

NO_x and SO₂ are gases that are formed during the process of combustion. In addition to being toxic of their own accord, both SO₂ and NO_x form secondary fine particle pollution,¹⁶ creating additional huge quantities of deadly fine particle pollution. In addition to improving reduction of fine particle emissions from industrial sources, strict control measures to drive down SO₂ and NO_x emissions must be installed to reduce the creation of secondary fine particle pollution. Nitrogen dioxide (NO₂) is the main oxide of nitrogen pollutant of concern.

Normally, ozone is not directly emitted by a source; it is formed at ground level when NO_x reacts with other chemicals in the air, including volatile organic compounds. (See more on ozone in section 7 below).

¹⁴ See: <https://www.hsph.harvard.edu/c-change/subtopics/coronavirus-and-pollution/>. See also: Cole, M., et al., *Air Pollution Exposure and COVID-19* (2020) available at: <http://ftp.iza.org/dp13367.pdf>; Liang, D., et al. *Urban Air Pollution May Enhance COVID-19 Case-Fatality and Mortality Rates in the United States* (2020) available at: <https://doi.org/10.1101/2020.05.04.20090746>; Tian, H., et al. (2020). *Risk of COVID-19 is associated with long-term exposure to air pollution* (2020) available at: <https://doi.org/10.1101/2020.04.21.20073700>.

¹⁵ Carbon monoxide (CO) and lead (Pb) have also been listed as criteria pollutants. Improvements in mobile source fuels and technologies have significantly reduced the risk posed by these pollutants.

¹⁶ Ewald, Ben., *The Health burden of fine particle pollution from electricity generation in NSW* (November 2018) p. 20. Available at: https://www.envirojustice.org.au/wp-content/uploads/2018/11/Ewald_B_2018_The_health_burden_of_fine_particle_pollution_from_electricity_generation_in_NSW.pdf.

Mercury (Hg) is well-known for its toxicity and, while not emitted by a broad range of sources, is nonetheless a pollutant of concern. Although mercury is released in much lower levels than PM, SO₂, NO_x and ozone, it is highly toxic and accumulates in both the environment and the body. Any release of mercury is significant. Specific highly toxic substances such as volatile organic compounds (VOC) are also a concern, both on their own and in the formation of ozone.

2.2 Monitoring and access to information

Air quality monitoring must be improved to effectively measure the health risk for at-risk communities. There is very little air pollution monitoring undertaken at roadsides in Sydney, where traffic is heavy and causes poor air quality in front of schools, kindergartens, residential facilities, aged-care facilities and hospitals. The City of Sydney Council, for example, has stated that the lack of monitoring in the inner-city areas of Sydney prevents the Council from taking measures to reduce air pollution.¹⁷

In addition to monitoring, access to information about air pollution is critical. Under their pollution licences, power stations in NSW are required to upload monitoring information on a monthly basis onto their websites. Access to information could be improved by aggregating this data onto a single EPA website, as is the case with real-time air pollution information from NSW government monitors.

Action: By September 2021, develop an air quality monitoring plan that increases the level of, and access to, air quality monitoring and information, including by:

- Installing and/or increasing permanent air quality monitoring stations in every community that is near a major industrial source of pollution, such as coal-fired power stations, with new monitors at Lake Macquarie and Lithgow.
- Implementing localised monitoring networks in areas with large traffic flow and with high wood-burning heater usage, including the use of low-cost monitors.
- Ensure access to monitoring data be made available in real-time, on a single website maintained by the EPA.
- Funding and implementing an *AirSmart* health promotion campaign to minimise the health impacts of poor air quality.¹⁸

2.3 Main sources of air pollution in NSW

NSW maintains an Air Pollutant Inventory for the greater metropolitan region (GMR), which includes Sydney, Newcastle and Wollongong regions. The NSW Air Pollutant Inventory is updated every seven

¹⁷ Jess Miller, NSW Health risks bushfire and drought inquiry: <https://www.parliament.nsw.gov.au/lcdocs/submissions/67634/0049%20Ms%20Jess%20Miller,%20Councillor,%20City%20of%20Sydney%20Council.pdf>

¹⁸ See: Asthma Australia, 'Now is the time to get AirSmart Australia', 1 September 2020: <https://asthma.org.au/about-us/media/now-is-the-time-to-get-airsmart-australia/>

years.¹⁹ Although the Air Emissions Inventory is useful, it does not include dangerous pollutants such as mercury. To fill in the gaps for mercury, data from the NPI is used.

According to the most recent Air Emissions Inventory, generation of electrical power from coal is the highest source of NO_x and SO₂ in the GMR, by significant amounts compared with the next highest sources. While coal-fired power stations are not the biggest source of direct PM_{2.5} pollution, since both SO₂ and NO_x form secondary PM_{2.5} pollution, coal-fired power stations are still a big source of PM_{2.5} in the GMR. For example, power station SO₂ produces close to 20 percent of PM_{2.5} at Richmond in Sydney’s north-west on an annual basis.²⁰ Overall, the coal industry in NSW, whether burning coal to generate electricity or coal mining, is the largest industrial contributor to NSW’s air pollution. This largely correlates with industry self-reporting in the most recent NPI data.

Table 1: Top three sources of key pollutants in NSW from the NSW Air Pollutant Inventory

PM ₁₀	PM _{2.5}	NO _x	SO ₂	Mercury
Bushfires and prescribed burning – 88,012,000kg (43%)	Bushfires and prescribed burning – 74,688,000kg (70.3%)	Coal-fired power stations – 139,000,000kg (45.7%)	Coal-fired power stations – 18,191,000 kg (84.9%)	Basic ferrous metal manufacturing – 230kg
Mining for coal – 68,020,000kg (33.2%)	Mining for coal – 10,238,000kg (9.64%)	Industrial vehicles and equipment – 30,767,000kg (10.1%)	Ships – 10,536,000 kg (4.52%)	Coal-fired power stations – 220kg
Marine Aerosol – 14,852,000kg (7.25%)	Solid Fuel Burning (Domestic) – 6,773,000kg (6.38%)	Bushfires and prescribed burning – 25,812,000kg (8.47%)	Aluminium production – 8,168,000 kg (3.5%)	Motor vehicles – 52kg

2.4 Where does the pollution go?

In the most recent assessment of air pollution from coal-fired power stations *Lethal Power: How Burning Coal is Killing People in Australia*,²¹ international air quality modelling experts conducted industry-standard air modelling. This modelling showed that air pollution from coal-fired power stations travels far beyond a power station’s location. Communities near the power station may be

¹⁹ The last inventory was completed for 2013, and published in 2019. See: NSW Environment Protection Authority (2019) Air Emissions Inventory for the Greater Metropolitan Region in New South Wales: 2013 Calendar Year Consolidated Natural and Human-Made Emissions, October 2019: <https://www.epa.nsw.gov.au/-/media/epa/corporate-site/resources/air/19p1917-air-emissions-inventory-2013.pdf>

exposed to the highest concentrations of air pollution under certain weather conditions,²² but transport of PM_{2.5} can extend for hundreds of kilometres and affect large populations in cities.²³

Lethal Power shows that, depending on wind direction and speed, PM_{2.5} pollution from coal-fired power stations in NSW travels across an enormous geographical area, contributing to poor air quality in Sydney, northwards towards Lismore and into South-East Queensland, and as far down as Shepparton in Victoria.²⁴ The highest concentrations of NO₂ air pollution from coal-fired power stations is in the airshed where the power stations is located. Not only does the pollution travel far, it is most concentrated at the source, disproportionately exposing people in nearby communities.

²⁴ Dr. Aidan Farrow, Andreas Anhäuser and Lauri Myllyvirta, *Lethal Power: How Burning Coal is Killing People In Australia* (August 2020), pp. 18-19., available at: <https://www.greenpeace.org.au/wp/wp-content/uploads/2020/08/GPAP-Lethal-Power-full-report.pdf>.

Air pollution from vehicles and wood heaters is largely localised. The heavier the traffic, the more air pollution is emitted. The most heavily impacted communities are often close to major ports, impacted by shipping and diesel-fuelled heavy vehicle movements. Smoke from wood heaters can sit in places such as Armidale for days in still weather, contributing to very poor air quality.²⁵ In NSW there is a paucity of ground-level air quality monitoring in urban areas with heavy traffic, and in areas where wood-burning heaters are predominantly used. The pervasive and widespread nature of pollution from coal-fired power stations means that even if localised sources of pollution like wood-burning and diesel trucks are reduced to zero, background concentrations of pollution will still pervade.

2.5 Health impacts of air pollution at existing concentrations

The International Agency for Research on Cancer classifies air pollution as a human carcinogen.²⁶ A 2019 global review of evidence found that air pollution can damage every organ and every cell in the human body.²⁷ In 2018, the director general of the World Health Organisation (WHO) declared air pollution a “public health emergency”.²⁸ Children and older people are most vulnerable to the health impacts of air pollution.

The most dangerous form of air pollution is PM_{2.5}. There is abundant evidence that PM_{2.5} exposure can cause adverse health effects and increased risk of death.²⁹ There is no lower threshold for these effects.³⁰ The science does not support that there is a safe level of exposure, so air quality standards are a reference level, not a safe level.³¹ Long term exposure is particularly damaging, even at lower

³¹ World Health Organization. Regional Office for Europe. (2006). *Air quality guidelines global update 2005: particulate matter, ozone, nitrogen dioxide and sulfur dioxide*. Copenhagen: WHO Regional Office for Europe. Available at: <https://apps.who.int/iris/handle/10665/107823>.

levels of pollution. A recent study from Queensland found that long-term exposure to PM_{2.5} was associated with increased all-cause mortality of two percent for each 1 µg/m³ increase in annual PM_{2.5}, even where PM_{2.5} levels were measured well-below air quality standards.³²

Research led by the University of Sydney has found up to a four percent increased risk of out-of-hospital cardiac arrest (OHCA) associated with every 10 µg/m³ increase in PM_{2.5}.³³ OHCA is a major medical emergency, with less than one in 10 people worldwide surviving these events.³⁴ Similarly, in Tasmania, where air pollution is mainly associated with wood heaters, a 10 µg/m³ increase in daily PM_{2.5} was associated with a 29 percent increase in hospital admissions for heart failure on the following day.³⁵

In 2019, the Harvard Chan School of Public Health published an analysis of more than 95 million Medicare hospital insurance claims for adults aged 65 or older in the United States from 2000 to 2012.³⁶ The researchers found that each 1 µg/m³ increase in PM_{2.5} was associated with 2,050 extra hospital admissions, 12,216 days in hospital, and USD\$31m in healthcare costs for diseases not previously associated with PM_{2.5} including sepsis, kidney failure, and urinary tract and skin infections. These associations remained even at daily PM_{2.5} concentrations below the WHO guideline. As such, the researchers concluded that substantial health and economic costs were linked to small PM_{2.5} short-term increases.

Children are particularly vulnerable to PM_{2.5} exposure due to the adverse effects on lung development. Australia's most common cause of general practitioner presentation in children under five is asthma and allergy. A 2015 Australian meta-analysis discovered that for every 2 µg/m³ incremental increase in chronic exposure to traffic-related particulate matter, the risk of developing subsequent asthma in childhood increased by 14 percent.³⁷ Reduced lung health and impaired development in children holds lifelong consequences, including an increased risk of cardiovascular disease and associated mortality as an adult.³⁸

Lung function

PM_{2.5} is not the only pollutant that adversely impacts health. At low concentrations, NO₂, SO₂ and O₃ can cause significant health problems. A number of Australian studies published in the last decade demonstrate statistically significant health impacts at pollutant concentrations well-below national standards for these pollutants.³⁹ Nitrogen dioxide is strongly associated with childhood asthma and impaired lung development, which can lead to lifelong adverse health effects and premature death.⁴⁰ Adverse neonatal outcomes, including preterm birth, low weight at birth and foetal growth restriction are associated with maternal exposures to NO₂, SO₂ and O₃.⁴¹ Laboratory confirmed paediatric influenza has also been associated with ozone.⁴² Middle-aged Australians exposed to nitrogen dioxide can experience exacerbations of current asthma, the incidence of new asthma, and atopy.⁴³ Long term exposure to SO₂, even at low concentrations, has been associated with cardiorespiratory mortality.⁴⁴

Developing but as-yet-unconfirmed evidence suggests a large effect from traffic-related air pollution damaging children's brain growth.⁴⁵ If confirmed, this would be the largest and most economically harmful health impact of current air pollution exposure.

3. Controlling pollution from coal-fired power stations

Coal-fired power stations are the most significant controllable source of air pollution in NSW, which can be greatly reduced with best practice control standards.

This section outlines the best available technologies for pollution control and timeframe for installing those controls to protect human and environmental health. We have included Victorian coal-fired power stations in this section to demonstrate that coordinated control of air pollution from coal-fired power stations in both states is possible.

3.1 Regulating emissions from coal-fired power stations

Australia’s risk-based approach to air pollution regulation falls well short when compared with international counterparts.⁴⁶ For several decades the US, EU, South Korea, China, Japan and other nations have required increasingly effective controls for PM, NO_x, SO₂, and mercury.

Emissions from coal-fired power stations must be set at limits that require the installation of best available pollution control technologies (BACT) described below. Pollution licences must impose a range of obligations that, among other things, require pollution controls and power station infrastructure to be regularly maintained to ensure that operations are run as cleanly as possible. Because much of the PM_{2.5} from combustion of coal is formed by subsequent reaction of SO₂ and NO_x in the atmosphere, BACT levels of SO₂ and NO_x pollution controls must be required to properly protect the public from adverse PM_{2.5} health impacts.

Table 2: Emission levels that can be achieved with installation of BACT for existing coal-fired power stations⁴⁷

	Annual Average (mg/m ³)	Short term (daily or reference test) (mg/m ³)
PM ⁴⁸	2-8	3-11
SO ₂ & SO ₃	10-130	25-165
NO _x (coal)	65-150	<85-165
NO _x (lignite)	<85-150	140-165
Hg (coal)	<1-4 ug/m ³	<1-4 ug/m ³
Hg (lignite)	<1-7 ug/m ³	<1-7 ug/m ³

Emissions limits in other countries for existing power stations retrofitted with BACT are in Table 3 below.

⁴⁶ Although the NSW regulatory frameworks require advances in pollution reduction to be made, this is not done.

⁴⁷ See: Commission Implementing Decision (EU) 2017/1442 of July 2017, establishing best available techniques (BAT) conclusions, under Directive 2010/75/EU of the European Parliament and of the Council, for large combustion plants. “BAT Associated Emission Levels, Section 2 “BAT Conclusions for the Combustion of Solid Fuels”, <https://eur-lex.europa.eu/legal-content/EN/TXT/?qid=1503383091262&uri=CELEX%3A32017D1442>

⁴⁸ The EU Directive assigns slightly less stringent limits (2-10 mg/m³; 3-11mg/m³) to plants with a heat input of less than 1000 MW of thermal input (approximately 280-320 MW electric output).

Table 3: Representative emission limits for existing coal-fired power stations in other jurisdictions

	SO ₂ (mg/m ³)	NO _x (mg/m ³)	PM (mg/m ³)	Hg (ug/m ³)
China ⁴⁹	35	50	10	30
Japan ⁵⁰	68.3	57.5	14.3	10
South Korea ⁵¹	142.5	102.5	10	50
EU ⁵²	130	150	8	2.0/4.0 ⁵³
U.S. ⁵⁴	640	640	23	1.7/15.3 ⁵⁵

Compare these limits to the current limits for coal-fired power stations in NSW in Table 4 below.

⁶³ Based on ratio of condensable to filterable emissions; USEPA data in MATS proceeding. Docket Number EPA-HQ-OAR-2009-0234-3038 "Coal PM Floor Analysis". Available at:

<https://www.regulations.gov/document?D=EPA-HQ-OAR-2009-0234-3038>

NB: PMf refers to filterable fine particle pollution. PMf+c refers to filterable and condensable fine particle pollution.

Action: By September 2021, establish a comprehensive plan that sets out specific and enforceable obligations for coal-fired power station operators to achieve BACT emissions levels, including the following elements:

- BACT short and medium-term emissions limits for PM₁₀, PM_{2.5}, SO₂, NO_x, and Hg.
- Continuous emission monitoring (CEMS) for CO₂, PMf, SO₂, NO_x, and Hg, to be installed, maintained and operated, with real-time posting on a publicly available website.
- A requirement that CEMS be maintained and operated in accordance with international best practices, including annual relative accuracy test audits and quarterly relative accuracy audits.⁶⁴
- Use of the U.S. National Institute of Standards and Technology (NIST) “non-nulling” or the equivalent reference method to measure stack flow rate of stack gases.⁶⁵
- A maintenance plan, with specified replacement of parts at intervals based conservatively on prior maintenance history and on-site storage of critical components affecting emissions (such as filter bags, SO₂ and NO_x reagents).
- An immediate reduction in generation to the lowest level necessary to maintain grid stability and initiation of shutdown procedures for any malfunction that cannot be resolved within a specified period of time.
- The use of the cleanest available fuels during any period where a pollution control is not operational (e.g., before the unit reaches the operating temperature needed by its selective catalytic reduction (SCR)).
- Immediate reporting of any upset conditions to the agency and the public. The agency should thereafter investigate and post the results of its review.
- Shutdown of the unit if monitoring device availability falls below acceptable levels.

⁶⁴ For example, the procedures required to be followed for CEMS in the US appear in 40. CFR part 60, Appendix F. i.e., https://www.law.cornell.edu/cfr/text/40/appendix-F_to_part_60

Gentry (2020) Faster, more accurate, stack-flow measurements, *Journal of the Air & Waste Management Association*, 70:3, 283-291: [10.1080/10962247.2020.1713249](https://doi.org/10.1080/10962247.2020.1713249)

Suggested installation schedule for coal-fired power stations in NSW and Victoria

Installing pollution controls in existing coal-fired power stations requires planning, both for power stations to prepare, contract, construct and test controls, and to ensure there is adequate electricity supply. This will require cooperation and scheduling between the operators and the Australian Energy Market Operator (AEMO).

In order to ensure adequate electricity supply during the “tie-in” period, that is, the time that it takes to bring pollution controls into the combustion process, specific retrofit dates should stagger installation of controls in the National Electricity Market (NEM). The schedule for taking units offline for installation and tie-in provides that this should happen in spring and autumn seasons when demand for electricity is lowest and there is (ordinarily) excess capacity in the NEM. The schedule limits installations to no more than one unit at any power station at any time and phases in the installation of those controls over several years.

There are several alternative approaches to scheduling the installation of pollution controls in NSW and Victoria. One option is to require each operator to control a set percentage of its generating capacity (nominally 25 percent) each year commencing three years after the date of regulatory or legislative changes to emissions limits. Another option is to set retrofit dates for specific plants, based on advice from AEMO, and policy preferences expressed in legislation or regulation. Among the policy choices is the issue of whether it is better to require control on the oldest or newest units. The schedule for installation below assumes that the newer units are chosen first. This is because newer units require lower maintenance, have less unplanned outages, and lower fuel costs. As such, newer units can be expected to run more and be dispatched more often, making the installation of pollution controls more effective in delivering the greatest pollution reduction.

Table 6: Suggested schedule for installation of pollution controls

State	Power Station	Coal type	Start of Operations	Capacity	Retrofit dates
NSW	Eraring	Black	1982-1984	4 x 720 MW	Spring 2024; Autumn 2025; Spring 2025; Autumn 2026
NSW	Bayswater	Black	1982-1984	4 x 660 MW	Spring 2025; Autumn 2026; Spring 2026; Autumn 2027
NSW	Liddell	Black	1971-1973	4 x 500 MW	N/A – retiring 2022
NSW	Mt Piper	Black	1993	2 x 700 MW	Spring 2024; Autumn 2025
NSW	Vales Point B	Black	1978	2 x 660MW	Spring 2026; Autumn 2027

VIC	Loy Yang B	Brown	1993-96	2 x 535 MW	Spring 2024; Autumn 2025

VIC	Yallourn W	Brown	1975-1982	2 x 375 MW 2 x 350 MW	Spring 2025; Autumn 2026; Spring 2026; Autumn 2027
-----	------------	-------	-----------	--------------------------	--

4. Controlling pollution from mining for coal

Mining for coal is a major source of PM₁₀ and PM_{2.5} pollution in NSW.⁶⁶ Communities in the Upper Hunter Valley experience the greatest burden of air pollution from mining for coal. According to the NSW EPA, open cut coal mines are responsible for about 90 percent of coarse particle pollution (PM₁₀) in the Upper Hunter Region.⁶⁷ In 2019, residents in the Upper Hunter Valley received more than 1000 air pollution alerts when national air quality standards for PM₁₀ were exceeded.⁶⁸ In 2018, a year without severe bush fires, six monitoring sites in the Upper Hunter Valley recorded PM₁₀ concentrations that exceeded the annual standard of 25 µg/m³.⁶⁹ The village of Camberwell experienced 44 days where PM₁₀ exceeded the 24-hour standard of 50 µg/m³.⁷⁰ Every exceedance of the standards represents a threat to human health. Using World Health Organization figures, Upper Hunter GPs have estimated that PM₁₀ pollution caused at least 160 premature deaths in the Upper Hunter between 2015 and 2019.⁷¹

Blast plumes from open cut mines are a public health threat.⁷² A poorly conducted blast releases a cloud of highly concentrated nitrogen dioxide that can travel up to 5km before dispersing.⁷³ There

have been well documented cases of mine workers hospitalised after exposure despite being 3 to 5km from the blast, or members of the public becoming unwell after driving through a plume.⁷⁴

The NSW EPA operates a monitoring and compliance program in the Hunter Valley to tackle excessive PM₁₀ levels from coal mines, called *Operation Bust the Dust*.⁷⁵ The program inspects mines on hot, dry and windy days, to check that mines are implementing control procedures to minimise coarse particle pollution. These measures include watering unsealed roads, avoiding dust-generating activities during windy weather and minimising the impact of drilling operations. Previous iterations of the program, *Dust Stop* and *Dust Patrol* have been ineffective at reducing the number of exceedances in the Hunter Valley. In 2019 and 2020, the EPA found most mines “used adequate controls on mining activities”.⁷⁶ However, the EPA also found that “due to the extremely dry and windy weather, dust was observed blowing off exposed areas on mine site”.⁷⁷ If existing pollution control requirements are insufficient to control pollution, more must be done.

The EPA’s enforcement powers and mechanisms should also be strengthened. This could include the issuing of stop work orders during periods of increased air pollution and unfavourable weather conditions, so that mining operations do not contribute to more dust in the air. In July 2019 the EPA fined the Mount Arthur open cut-coal mine, near Muswellbrook, \$15,000 for causing excessive dust pollution on a windy day in October 2018.⁷⁸ It appears that Mount Arthur operators did not adapt its pollution control practice to minimise dust despite having received a January 2018 Penalty Notice for a similar alleged offence in 2017.⁷⁹ Such EPA compliance orders have been widely criticised by doctors and community leaders as insufficient to incentivise effective pollution control practices.⁸⁰

Action: By September 2021, implement a comprehensive program to control coarse particle pollution from coal mines, with a focus on the Upper Hunter Valley, including the following elements:

- A cumulative impacts approach to new mining project assessments.

⁷⁴ ABC News, 2013, “Upper Hunter miners exposed to toxic fumes,” 20 September 2013, available at: <http://www.abc.net.au/news/2013-09-20/upper-hunter-miners-exposed-to-toxic-fumes/4972192>; McCarthy J, 2014, “Mine blast gone wrong spews toxic cloud”, Sydney Morning Herald, 21 February 2014, available at <http://www.smh.com.au/environment/mine-blast-gone-wrong-spews-toxic-cloud-20140221-335rf.html>; Latimer, C., 2014, “Wambo coal mine fined over blast incident”, Australian Mining, 8 August 2014, available at: <https://www.australianmining.com.au/news/%e2%80%8bwambo-coal-mine-fined-over-blast-incident-2/>; Kelly M, 2013, “Effects of mine blasts worry residents”, Newcastle Herald, 12 May 2013.

- Enforcing a 10km buffer zone between communities and new open cut mines.
- A ban on new mine project approvals in areas where air quality standards are already exceeded.
- An increase in the EPA's *Bust the Dust* program inspections and enforcement staff.
- Enforcement of stop work orders during periods of increased air pollution and unfavourable weather conditions.
- Substantially increased penalties for excessive dust emissions and inadequate pollution control practices.

Load Based Licensing

The 'polluter pays' principle dictates that those who generate pollution and waste should bear the cost of containment, avoidance or abatement.⁸¹ The NSW Load-Based Licensing scheme requires polluters to pay licence fees based on the amount of the pollution produced. It provides a financial incentive for polluters to reduce their emissions of toxic pollution, adopt cleaner technologies, and to determine the most cost effective way of doing so. At present, coal mines are exempt from the Load-Based Licensing Scheme.⁸²

The NSW Load-Based Licensing scheme has been under review since late 2016.⁸³ In redeveloping the Load-Based Licensing scheme, the NSW government should ensure that fees are set at a level that incentivises pollution reduction and internalises the cost of the pollution. For example, existing fees have not incentivised BACT installation from coal-fired power stations. It has been estimated using data from the Australian Academy of Technological Science and Engineering (ATSE) that licence fees would have to increase by a factor of almost 50 to properly internalise the health costs created by the NSW power stations.⁸⁴

Action: By September 2021, update the Load-Based Licencing scheme to incentivise pollution reductions from industry, including the following elements:

- Removal of the licence fee exemption for pollution emitted by coal mines and associated infrastructure (trucks, conveyors, load-out facilities and trains).
- Increase licence fees to a level that internalises the health costs of pollution.
- Remove the fee rate threshold so the cost of a unit of pollution is consistent and not determined by source.

5. Controlling pollution from motor vehicles and transport

Across the NSW GMR on-road mobile sources account for 15 percent of NO₂ and 1.7 percent of PM_{2.5}, but in Sydney where the greatest population lives the proportions are 53 percent of NO₂ and 9.3 percent of PM_{2.5}.⁸⁵ In 2005, the health costs of motor vehicle pollution across Sydney were estimated to be \$1.5 billion per year.⁸⁶ Modern vehicles are much cleaner than older vehicles, but there is no systematic mechanism to remove highly polluting vehicles from the road fleet. This is a problem for people living, working or travelling on busy roads, which is potentially amplified by the growing number of road tunnels.

Australia has the lowest rank out of the 35 OECD countries for fuel quality.⁸⁷ Diesel vehicles emit much higher amounts of NO_x than petrol vehicles. Many OECD countries and cities are phasing out diesel vehicles due to the health impacts associated with diesel emissions.⁸⁸ Rather than acting in a manner consistent with its OECD counterparts, Australia is increasing the amount of diesel vehicles on its roads.⁸⁹ California and other US state regulators now recognise diesel particulate matter (DPM) as a special class of particulates. More than 90 percent of fine particle pollution from diesel combustion is less than 1 micrometre in diameter, a subset of PM_{2.5} that is considered even more toxic. In 2012, the World Health Organization's International Agency for Research on Cancer (IARC)

released its research assessing the health impacts of air pollution from diesel.⁹⁰ IARC’s extensive literature review led to the conclusion that diesel engine exhaust is “carcinogenic to humans”.⁹¹

In order to reduce air pollution from vehicle emissions, governments in Britain and the European Union created “Clean Air Zones”, or “Low Emission Zones”.⁹² These Zones are established in densely populated areas, particularly near vulnerable community locations such as schools and childcare centres. Clean Air Zones implement a “polluter pays” principle by imposing a fee on polluting vehicle operators who drive within or through the Zone. The fee can be initially targeted at diesel freight trucks and be increased progressively to include other forms of vehicles. Between February 2017 and February 2020, there has been a 39 micrograms per cubic metre reduction in roadside concentrations of nitrogen dioxide in London’s Ultra Low Emissions Zone (ULEZ), a reduction of 44 percent.⁹³ The London ULEZ scheme contains fee exemptions for residents, vehicle operators with a disability, taxis, and other not-for-profit community uses such as school transport to ensure that it is an equitable policy that does not adversely affect the everyday people whose health the scheme is designed to protect.⁹⁴

Idling – running a vehicle’s engine while it is stationary – can also lead to poor local air quality with serious health risks, particularly for vulnerable populations. In the United States, idling has been identified as a significant factor in higher pollution levels in and around schools.⁹⁵ More than 23 US states limit vehicle idling by some or all vehicles.⁹⁶ Eighteen US states implement schemes involving grants, loans, or tax credits to provide incentives for adopting idle reduction technologies for heavy vehicles. Significant child health improvements have been associated with the Californian EPA policies that reduced children’s exposure to traffic-related air pollution (TRAP).⁹⁷ The Californian EPA policies

resulted in the development of larger, healthier lungs in children, with health benefits that extend into adulthood, including a reduced risk of cardiovascular disease and associated mortality.

Vehicle emissions can be reduced by other mechanisms, including by implementing Euro 6 standards for passenger and light vehicles, and Euro V1 standards for heavy vehicles. The EU has consistently reviewed its vehicle emissions standards of both petrol and diesel vehicles to drive down NO_x emissions.⁹⁸ The most recent standard imposed an emission reduction limit for light diesel vehicles of 56 percent, from 0.18 g/km (Euro 5 Standard) to 0.08 g/km (Euro 6).⁹⁹ A significant factor in the success of reducing NO_x emissions from vehicles is using fuels with very low sulfur content.¹⁰⁰ Europe commenced phasing-in virtually sulfur-free petrol and diesel fuels – less than 10ppm – in 2005. Australia currently implements the less-stringent Euro 5 standards for light and heavy vehicles.¹⁰¹ The Ministerial Forum on Vehicle Emissions is currently undertaking a review to consider whether Australia should adopt the Euro 6 Standards for light vehicle and Euro VI standards for heavy vehicles. Fuel standards are set the federal level,¹⁰² however the Ministerial Forum on Vehicle Emissions review is a good opportunity for the NSW government to make submissions on the necessity of adopting the Euro 6 standards.

The rail sector is another source of uncontrolled air pollution in NSW.¹⁰³ Rail freight lines run through densely populated suburbs exposing many people to toxic diesel exhaust. Europe and the United States have had locomotive emissions standards for in place for two decades.¹⁰⁴ The US EPA rule cuts PM emissions from these engines by as much as 90 percent, NO_x emissions by as much as 80 percent, and reduces idling from locomotives.¹⁰⁵

Action: By September 2021, develop a comprehensive plan to reduce vehicle pollution, with a focus on vehicle pollution hotspots, including the following elements:

⁹⁸ For a history of vehicle emissions reductions in the EU, and elsewhere, see:

¹⁰⁵ See: <https://www.epa.gov/regulations-emissions-vehicles-and-engines/regulations-emissions-locomotives>

- Low emissions/clean air zones targeting diesel freight trucks in high-traffic urban areas.
- Anti-idling regulations to require engines be stopped when a vehicle is stationary for more than 1 minute, particularly near vulnerable community locations such as schools and childcare centres.
- Incentives for freight operators to upgrade to Euro 6/VI compliant vehicles.
- Introduction of US Tier 2 emissions standards for locomotives.

6. Controlling pollution from domestic solid fuel burning

Solid fuel burning - that is, wood-burning heaters - significantly impacts local air quality throughout NSW.¹⁰⁶

The principle control measures for wood heater pollution include: regulating the use of existing wood heaters, phasing out wood heaters in residential areas, and offering incentives to upgrade insulation and install clean heat pumps. Numerous states in the US have enacted regulations that phase out wood heaters, or ban solid fuel burning outright during periods of increased air pollution risk or unfavourable weather conditions.¹⁰⁷ Some US state building codes also prohibit the construction of homes that rely on solid fuel as a heating source.¹⁰⁸ These control measures are most effective when accompanied by public education and communication about the health risks associated with wood smoke.¹⁰⁹

Australia's most successful wood smoke-reduction program was in Launceston, Tasmania. The program focused on public communications about the health impacts of wood smoke pollution and replacing wood heaters with clean heating alternatives. About 2,000 households received subsidies of \$500 to remove wood heaters, while many more households replaced wood heaters with clean heating alternatives entirely at their own expense.¹¹⁰ These interventions dramatically accelerated a general trend towards using heat pumps rather than wood heaters. As such, wood heater prevalence

¹⁰⁶ See, for example, the NSW EPA Upper Hunter Wood Smoke Community Research Project: <https://www.epa.nsw.gov.au/your-environment/air/reducing-wood-smoke-emissions/upper-hunter-wood-smoke-community-research-project>.

¹⁰⁷ Modelling of air pollution may conclude that, if solid fuel appliances are permitted, the city or town will violate air quality standards, so the bans or restrictions are imposed as preventative measures to maintain compliance.

¹⁰⁸ See, for example: Washington State Energy Code, Sections R303.10.2 and R303.10.3: <https://up.codes/viewer/washington/irc-2015/chapter/3/building-planning#R303>

¹¹⁰ Robinson, D.L. What makes a Successful Woodsmoke-Reduction Program? *Air Quality and Climate Change* 2016, 50, 20-28.

fell from 66 percent to 30 percent of all households and average particulate air pollution during winter was reduced by 40 percent ($44 \mu\text{g}/\text{m}^3 - 27 \mu\text{g}/\text{m}^3$).¹¹¹ This reduced wintertime deaths from respiratory disease by 28 percent and cardiovascular disease deaths by 20 percent.¹¹² Year round, for men, the reductions were 23 percent (respiratory), 18 percent (cardiovascular) and 11.4 percent (all deaths).¹¹³

The 2019 'Clean Air Plan for Sydney' authored by 35 expert air pollution scientists recommended legislation that works towards eliminating the use of wood heaters in urban areas.¹¹⁴ One way to achieve this is to require wood heaters be removed when houses are sold. A 2011 consultancy report by AECOM Australia Pty Ltd for the NSW Office of Environment and Heritage concluded that a wood heater phase out, which banned the installation new wood heaters and required existing ones to be removed when houses are offered for sale, would yield the greatest cost-benefit of all wood smoke control measures, delivering a net-benefit of over \$7.1 billion out to 2030.¹¹⁵

Action: By September 2021, implement a plan to phase-out wood heaters, including the following elements:

- Progressive restrictions on the use of wood heaters during periods of increased air pollution risk and/or unfavourable weather conditions.
- Require the removal of wood heaters from homes upon sale.
- Subsidise insulation upgrades and heat pump installations for houses that remove wood heaters.
- Phase out the installation of wood heaters.

7. Controlling ozone pollution

Ozone (O₃) is a secondary pollutant – it is ordinarily not emitted directly by industrial process such as burning coal or by vehicles.¹¹⁶ Ozone is a colourless gas formed when NO_x and volatile organic compounds (VOC) react in sunlight. VOCs are a class of chemicals used across and emitted by many sources, including hydrocarbons from vehicle exhaust pipes.

Unhealthy concentrations of O₃ can form at considerable distances from direct sources of pollution, increasing the risk of unhealthy exposure to ozone in air that does not have industrial sources of air pollution or heavy traffic.

As explained above, O₃ impacts the airways and lungs, increasing susceptibility to lung infections and aggravating lung diseases. O₃ also reduces the photosynthesis and growth of certain agriculture crops and flora, increasing the risk of disease and insect damage.¹¹⁷

The best strategy to reduce ozone concentrations is to reduce NO_x and VOC emissions. Reducing NO_x emissions from large sources of NO_x emissions such as coal-fired power stations by installing SCR has the co-benefit of reducing both O₃ and PM_{2.5}. However, reducing NO_x alone does not automatically reduce O₃, and can in fact increase O₃. Aggressive air pollution controls have been implemented in China to reduce NO_x emissions, but significant ozone concentrations are pervasive and increasing.¹¹⁸ The best way to reduce O₃ is for integrated pollution controls to be implemented that reduce NO_x and VOCs.

7.1 Reducing VOCs

There are a range of specific VOC emission control methods to reduce the diverse sources and composition of VOCs by combining several of the following:¹¹⁹

- **Improve work practice standards** by requiring VOC capture into hood or duct work to minimise fugitive emissions.

¹¹⁶ This section focuses on ground level, or tropospheric, ozone, which is distinguished from stratospheric ozone that protects us from the harmful ultraviolet effects of the sun's rays. A good mnemonic to distinguish the two types of ozone is: "Ozone in the blue is good for you. Ozone on the ground will get you down."

¹¹⁷ Avnery, Shiri, et al., 'Global crop yield reductions due to surface ozone exposure: 2. Year 2030 potential crop production losses and economic damage under two scenarios of O₃ pollution' (2011) 45 *Atmospheric Science* 2297.

¹¹⁸ University of Colorado at Boulder, Cooperative Institute for Research in Environmental Sciences, 2018, "China is Hot Spot of Ground-Level Ozone Pollution". Retrieved from <https://cires.colorado.edu/news/china-hot-spot-ground-level-ozone-pollution>; Ke Li, et al., "Anthropogenic Drivers of 2013-2017 Trends in Summer Surface Ozone in China", 2019. Proceedings of the National Academy of Sciences. Retrieved from: <https://www.pnas.org/content/116/2/422>; ¹¹⁸ Clean Air Asia, "China Air 2019: Air Pollution Prevention and Control Progress in Chinese Cities". Nationally, annual average ozone concentrations increased from 149 ug/m³ in 2017 to 151 ug/m³ in 2018.

¹¹⁹ See: U. S. Environmental Protection Agency, *Generic Chemical Rules for Stationary Sources of Air Pollution*: <https://www.epa.gov/stationary-sources-air-pollution/generic-chemical-rules-stationary-sources-air-pollution>; R. Avery, "Reactivity-Based VOC Control for Solvent Products: More Efficient Ozone Reduction Strategies", 2006. Environmental Science and Technology. Volume 40, pages 4845-4850: <https://pubs.acs.org/doi/pdf/10.1021/es060296u?rand=umc9039z&>

- **Pollution prevention techniques** requiring a switch from more hazardous or reactive chemical to a less hazardous or water-based product, or requiring fewer chemicals in the manufacturing process.
- **Limit emissions for each sector** expressed as kilograms of VOC per litre or kilogram of product applied.
- **Limit vapour pressure of petrol** especially during warm summer months, to reduce evaporative losses during the filling of storage tanks and refuelling of vehicles.
- **Minimum percentage** capture and destruction efficiency in an incinerator, expressed as minimum 95 percent capture, destruction and removal efficiency of VOC emissions.

7.2 Reducing NO_x

In addition to NO_x pollution controls that must be installed in coal-fired power stations described above, other combustion processes, industrial boilers and vehicle NO_x emissions can be controlled by:

- **Improving combustion efficiency**, keeping the boiler or vehicle well maintained and tuned to optimal performance standards;
- **Reducing combustion temperature** to lower NO_x emissions, ensuring that boilers are tuned to prevent increase of carbon monoxide concentrations;
- **Reducing the sulfur content in fuel** for installing catalytic devices that can effectively control NO_x emissions. High sulfur poisons catalysts, rendering them less effective, decreasing their operating life, and increasing maintenance costs;
- **Installing selective catalytic reduction** in industrial facility boilers and solid waste incinerators which can reduce NO_x emissions by 90 percent or higher.

Action: By September 2021, require industry emission standards for VOCs and NO_x consistent with best international practices, including the following elements:

- A requirement for leak detection systems to be installed on all oil refineries and gas plants to reduce VOC emissions.¹²⁰
 - VOC emissions limits and capture efficiency targets by sector.¹²¹
 - A requirement for the installation of SCR technology on all industrial boiler facilities.
-

¹²⁰ See: U. S. Environmental Protection Agency, *Leak Detection and Repair: A Best Practices Guide*: <https://www.epa.gov/sites/production/files/2014-02/documents/ldarguide.pdf>

¹²¹ See: U. S. Environmental Protection Agency, *Generic Chemical Rules for Stationary Sources of Air Pollution*: <https://www.epa.gov/stationary-sources-air-pollution/generic-chemical-rules-stationary-sources-air-pollution>

8. National ambient air standards

The *National Environment Protection (Ambient Air Quality) Measure* (the NEPM) is intended to provide a nationally consistent framework for monitoring and reporting on ambient air quality. The NEPM is reflected in state law through regulations.¹²² The monitoring and reporting functions of the NEPM in NSW are carried out by the EPA. Ambient air monitors owned and operated by EPAs are largely implemented in order for states to fulfil their monitoring and reporting obligations under the NEPM.

NEPM standards must be set at a level where air pollution exposure is reduced as far as possible. In 2015, Australia adopted a standard for annual PM_{2.5} at 8µg/m³.¹²³ The NSW government should ensure that the NEPM for annual PM_{2.5} is lowered to 7µg/m³ and 24-hour PM_{2.5} is lowered to 20µg/m³, as proposed in the 2015 amendment.¹²⁴

Ambient air quality standards for the other key pollutants that reflect a minimum adverse impact on human health as agreed on by Australian health professional are as follows:¹²⁵

Table 7: Recommended safe ambient air quality standards to protect health

Standard (in parts per billion)	Limit
SO ₂ 1-hour	60 (as 99 th centile of daily worst hour)
SO ₂ 24-hour	8 (no exceedances)
NO ₂ 1-hour	72 (as 99 th centile of daily worst hour)
NO ₂ annual	9 (no exceedances)
O ₃ 1-hour	70

The NSW government must also commence monitoring, assessment and reporting of Upper Hunter air pollution under the NEPM. Section 3 of the NEPM requires New South Wales to monitor, assess and report a range of air pollution indicators. The population of The Upper Hunter Valley region (which in the 2016 Urban Centre and Locality statistical level totalled 30,658) significantly exceeds the 25,000 population threshold to trigger the mandatory monitoring, assessment and reporting of air pollution under the NEPM AAQ.

¹²² In NSW: *National Environment Protection Measure (NSW) Act 1995* (NSW).

¹²⁴ Variation to the National Environment Protection (Ambient Air Quality) Measure 2015: <https://www.legislation.gov.au/Details/F2016L00084>. See also: <https://www.nepc.gov.au/resource/variation-ambient-air-quality-nepm-%E2%80%93-particles-standards>

¹²⁵ Clare Walter, Maxwell Smith et al. (2019) Health-based standards for Australian regulated thresholds of nitrogen dioxide, sulfur dioxide and ozone: Expert Position Statement 2019: <https://www.envirojustice.org.au/wp-content/uploads/2019/11/Expert-Position-Statement-PDF.pdf>

Action: By September 2021, legislate ambient air quality standards for SO₂, NO₂ and O₃ to the values in Table 7, and regulate key emissions point-sources to ensure they are met.

Action: Periodically review the ambient standards based on epidemiological data, and revise/strengthen as appropriate. At a minimum, this should be completed every 5-7 years.

Action: Integrate the Upper Hunter Monitoring Network into NSW NEPM reporting.

9. Timeframes and targets

Timeframes and targets to achieve reduction in air pollution to best practice control standards must be set by the NSW government. Each airshed has unique characteristics based on the source of air pollution, the geography of the area, and meteorological patterns. These characteristics inform the types of air pollution control measures that should be adopted, the emissions reduction framework that is required, and factor for the meteorological conditions that can exacerbate pollutant concentrations.

To develop the air pollution reduction target for a given airshed the following questions must be answered:

- What levels of pollution reduction are required?
- How many tonnes of pollution must be removed from the airshed in order to meet (and sustain) health-based ambient air pollution standards?
- Based on economic forecasts, how will the mix of air pollution sources change in the future?
- What do these changes suggest for the need to adopt more stringent standards and control measures in the future to maintain compliance with ambient pollution standards?
- What control measures might provide concurrent reductions of many pollutants?

The timeframe to achieve reduction targets also varies by airshed, pollutants, and the mix of sources that contribute to pollution. Pollutant concentrations that are much higher than public health standards require more time to achieve than concentrations that are just above those standards.

Establishing timeframes to reduce pollution helps to provide transparency to the public. Timeframes are important for businesses who produce air pollution to meet stronger standards by planning for the installation of pollution controls.

The two main practices for a compliance timeframe are:

1. USA: set an effective compliance date three to five years into the future.¹²⁶ Sources that indicate that this timeframe is too tight must be put on a negotiated, enforceable consent agreement that provides the conditions that must be met in the interim, and which sets a final compliance date after which the requisite equipment must be installed or the source must close down.
2. EU: Typically, each Directive sets an effective compliance date three to five years into the future. Directives are implemented by each Member State. For sources who indicate that this timeframe is too tight, an individual agreement is negotiated which allows the source to operate for a designated number of hours over the three-year period, after which time the emissions standard must be met or the source must close.¹²⁷

Either the USA or EU option is acceptable. Both options provide certainty to the public and to businesses. Both options set a compliance date for reduction in pollution or the source of the pollution must close.

Action: By September 2021, prepare an outline of timelines and targets for achieving reduction in air pollution to best practice control standards for NSW.

¹²⁶ Section 110 of the US Clean Air Act requires state and local agencies to prepare new/revise existing air quality plans within three years after the adoption of a new or revised ambient air quality standard. For industrial and power plant standards, each standard (New Source Performance Standards, MACT and RACT) includes a date by which affected sources must comply with them. Sources that are unable to meet such date must negotiate an individual, enforceable consent agreement that spells out the conditions that the source must meet, and the timeframe for which the source must install controls or cease operation.

¹²⁷ European Union, Industrial Emissions Directive. Overview of Directive: <https://ec.europa.eu/environment/industry/stationary/ied/legislation.htm>. See also, frequently asked questions about the Directive: <https://ec.europa.eu/environment/industry/stationary/ied/faq.htm>. The three to five year derogations are negotiated between each Member State and the affected source.
